The Erdős-Selfridge Function

Definition:

Let $lpf(n)$ be the least prime factor of the integer n .

Then $g(k)$ is the smallest integer, with $g(k) > k + 1$, such that

$$lpf\left(\binom{g(k)}{k}\right) > k.$$

Why?

- Paul Erdős posed the $g(k)$ problem in 1969.
- It's in the Online Encyclopedia of Integer Sequences: OEIS A003458

Examples of $g(k)$ using Pascal's Triangle

$k =$	0	1	2	3	4	5	6	7
	1							
	1	1						
	1	2	1					
	1	3	3	1				
	1	4	6	4	1			
	1	5	10	10	5	1		
	1	6	15	20	15	6	1	
	1	7	21	35	35	21	7	1

$g(1) = 3$ since $3 > 1 + 1$ and $\binom{3}{1} = 3$ with $lpf(3) = 3 > 1$.

Examples of $g(k)$ using Pascal's Triangle

$k =$	0	1	2	3	4	5	6	7
	1							
	1	1						
	1	2	1					
	1	3	3	1				
	1	4	6	4	1			
	1	5	10	10	5	1		
	1	6	15	20	15	6	1	
	1	7	21	35	35	21	7	1

$g(1) = 3$ since $3 > 1 + 1$ and $\binom{3}{1} = 3$ with $lpf(3) = 3 > 1$.

$g(2) = 6$ since $6 > 2 + 1$ and $\binom{6}{2} = 15$ with $lpf(15) = 3 > 2$.

Examples of $g(k)$ using Pascal's Triangle

$k =$	0	1	2	3	4	5	6	7
	1							
	1	1						
	1	2	1					
	1	3	3	1				
	1	4	6	4	1			
	1	5	10	10	5	1		
	1	6	15	20	15	6	1	
	1	7	21	35	35	21	7	1

$g(1) = 3$ since $3 > 1 + 1$ and $\binom{3}{1} = 3$ with $lpf(3) = 3 > 1$.

$g(2) = 6$ since $6 > 2 + 1$ and $\binom{6}{2} = 15$ with $lpf(15) = 3 > 2$.

$g(3) = 7$ since $7 > 3 + 1$ and $\binom{7}{3} = 35$ with $lpf(35) = 5 > 3$.

Examples of $g(k)$ using Pascal's Triangle

$k =$	0	1	2	3	4	5	6	7
	1							
	1	1						
	1	2	1					
	1	3	3	1				
	1	4	6	4	1			
	1	5	10	10	5	1		
	1	6	15	20	15	6	1	
	1	7	21	35	35	21	7	1

$g(1) = 3$ since $3 > 1 + 1$ and $\binom{3}{1} = 3$ with $lpf(3) = 3 > 1$.

$g(2) = 6$ since $6 > 2 + 1$ and $\binom{6}{2} = 15$ with $lpf(15) = 3 > 2$.

$g(3) = 7$ since $7 > 3 + 1$ and $\binom{7}{3} = 35$ with $lpf(35) = 5 > 3$.

$g(4) = 7$ since $7 > 4 + 1$ and $\binom{7}{4} = 35$ with $lpf(35) = 5 > 4$.

Computational Results: Ecklund, Erdős, Selfridge (1974)

B: $g(k)$ exceeds the search bound of 2500000

$g(k)$ is troublesome

More Computations

Scheidler and Williams (1992) used Kummer's theorem to construct a sieve algorithm to compute $g(k)$ for all $k \leq 140$.

Typo:
 $g(114) = 59819\ 90286\ 02614$.

256

RENATE SCHEIDLER AND HUGH C. WILLIAMS

$g(k)$ for k up to 200 (SW92/LSW97)

99 is Trouble!

New Computational Results

- We have a new algorithm to compute $g(k)$ in sublinear time.
- Our approach is also built on Kummer's theorem.

- We use a space-saving wheel datastructure.
- We found $g(k)$ for all $k \leq 272$ using one processor, and for $k = 273$ to $357+$ in parallel (so far).

Webster's Conjecture

Webster's Conjecture (2019)

$g(k) + 1 = g(k + 1)$ infinitely often.

$$g(2) + 1 = g(3) = 7$$

$$g(10) + 1 = g(11) = 47$$

$$g(18) + 1 = g(19) = 2099$$

$$g(36) + 1 = g(37) = 152189$$

$$g(350) + 1 = g(351) = 1097023825535035977424062277983$$

Computational Results - So Far

$g(k)$ for all k up to 357

Kummer's Theorem

Theorem (Kummer).

Let $k < n$ be positive integers, and let p be a prime $\leq k$.
Let $t \geq \lfloor \log_p k \rfloor + 1$ be an integer and write

$$k = \sum_{i=0}^t a_i p^i \quad \text{and} \quad n = \sum_{i=0}^t b_i p^i$$

as the base- p representations of k and n , respectively.

Then p does not divide $\binom{n}{k}$ iff $b_i \geq a_i$ for all $i \leq t$.

Kummer's Theorem - Examples

$k = 10, n = 12, p = 5$:

$k = 20_5, n = 22_5$ so 5 **does not** divide $\binom{12}{10} = 66$.

Kummer's Theorem - Examples

$k = 10, n = 12, p = 5$:

$k = 20_5, n = 22_5$ so 5 **does not** divide $\binom{12}{10} = 66$.

$k = 10, n = 12, p = 3$:

$k = 101_3, n = 110_3$ so 3 **does** divide $\binom{12}{10} = 66$.

Kummer's Theorem - Examples

$k = 10, n = 12, p = 5$:

$k = 20_5, n = 22_5$ so 5 **does not** divide $\binom{12}{10} = 66$.

$k = 10, n = 12, p = 3$:

$k = 101_3, n = 110_3$ so 3 **does** divide $\binom{12}{10} = 66$.

Idea:

For each $p \leq k$, we get a list of *acceptable residues* modulo $p^{\lfloor \log_p k \rfloor + 1}$.

Combine these residues modulo

$$M_k := \prod_{p \leq k} p^{\lfloor \log_p k \rfloor + 1}$$

using the Chinese remainder theorem to create a **sieve problem**.

Kummer's Theorem - Examples

$k = 10, n = 12, p = 5$:

$k = 20_5, n = 22_5$ so 5 **does not** divide $\binom{12}{10} = 66$.

$k = 10, n = 12, p = 3$:

$k = 101_3, n = 110_3$ so 3 **does** divide $\binom{12}{10} = 66$.

Idea:

For each $p \leq k$, we get a list of *acceptable residues* modulo $p^{\lfloor \log_p k \rfloor + 1}$.

Combine these residues modulo

$$M_k := \prod_{p \leq k} p^{\lfloor \log_p k \rfloor + 1}$$

using the Chinese remainder theorem to create a **sieve problem**.

$g(k)$ is the **smallest acceptable residue modulo M_k** with
 $g(k) > k + 1$.

Example with $k = 10$

$p = 2$, $k = 1010_2$:

$1010_2, 1011_2, 1110_2, 1111_2$

(4 residues mod $2^4 = 16$)

$p = 3$, $k = 101_3$:

$101_3, 102_3, 111_3, 112_3, 121_3, 122_3, 201_3, 202_3, 211_3, 212_3, 221_3, 222_3$

(12 residues mod $3^3 = 27$)

$p = 5$, $k = 20_5$:

$20_5, 21_5, 22_5, 23_5, 24_5, 30_5, 31_5, 32_5, 33_5, 34_5, 40_5, 41_5, 42_5, 43_5, 44_5$

(15 residues mod $5^2 = 25$)

$p = 7$, $k = 13_7$:

$13_7, 14_7, 15_7, 16_7, 23_7, 24_7, 25_7, 26_7, 33_7, 34_7, 35_7, 36_7, 43_7, 44_7, 45_7,$
 $46_7, 53_7, 54_7, 55_7, 56_7, 63_7, 64_7, 65_7, 66_7$

(24 residues mod $7^2 = 49$)

Algorithm Example with $k = 10$

$$M_{10} = 16 \cdot 27 \cdot 25 \cdot 49 = 529200.$$

$R_{10} := 4 \cdot 12 \cdot 15 \cdot 24 = 17280$ is *too many* residues to check.

Algorithm Example with $k = 10$

$$M_{10} = 16 \cdot 27 \cdot 25 \cdot 49 = 529200.$$

$R_{10} := 4 \cdot 12 \cdot 15 \cdot 24 = 17280$ is *too many* residues to check.

We estimate that $g(10) \leq 306.27$. (roughly $k \cdot M_k / R_k$)

Algorithm Example with $k = 10$

$$M_{10} = 16 \cdot 27 \cdot 25 \cdot 49 = 529200.$$

$R_{10} := 4 \cdot 12 \cdot 15 \cdot 24 = 17280$ is *too many* residues to check.

We estimate that $g(10) \leq 306.27$. (roughly $k \cdot M_k / R_k$)

We will look modulo $N = 2^4 \cdot 3 \cdot 7 = 336$, which divides M_k , and search among the residues modulo 336 instead:

$10, 11, 14, 15$ modulo 16

$1, 2$ modulo 3

$3, 4, 5, 6$ modulo 7

For a total of only 32 residues to check.

Algorithm Example with $k = 10$

$$M_{10} = 16 \cdot 27 \cdot 25 \cdot 49 = 529200.$$

$R_{10} := 4 \cdot 12 \cdot 15 \cdot 24 = 17280$ is *too many* residues to check.

We estimate that $g(10) \leq 306.27$. (roughly $k \cdot M_k / R_k$)

We will look modulo $N = 2^4 \cdot 3 \cdot 7 = 336$, which divides M_k , and search among the residues modulo 336 instead:

$10, 11, 14, 15$ modulo 16

$1, 2$ modulo 3

$3, 4, 5, 6$ modulo 7

For a total of only 32 residues to check.

We use a wheel data structure to do this efficiently.

Algorithm Example with $k = 10$

$$M_{10} = 16 \cdot 27 \cdot 25 \cdot 49 = 529200.$$

$R_{10} := 4 \cdot 12 \cdot 15 \cdot 24 = 17280$ is *too many* residues to check.

We estimate that $g(10) \leq 306.27$. (roughly $k \cdot M_k / R_k$)

We will look modulo $N = 2^4 \cdot 3 \cdot 7 = 336$, which divides M_k , and search among the residues modulo 336 instead:

$10, 11, 14, 15$ modulo 16

$1, 2$ modulo 3

$3, 4, 5, 6$ modulo 7

For a total of only 32 residues to check.

We use a wheel data structure to do this efficiently.

How did we pick $N = 336$?

Knapsack

- Choosing prime rings to include in N is a variation of the *knapsack problem*, which is NP-complete.

Knapsack

- Choosing prime rings to include in N is a variation of the *knapsack problem*, which is NP-complete.
- For a ring with modulus p^e and $r(p, e)$ residues,

$$\text{Ring Size} := \log(p^e) = e \log p.$$

$$\text{Ring Value} := \log(p^e / r(p, e)) = e \log p - \log r(p, e).$$

Knapsack

- Choosing prime rings to include in N is a variation of the *knapsack problem*, which is NP-complete.

- For a ring with modulus p^e and $r(p, e)$ residues,

$$\text{Ring Size} := \log(p^e) = e \log p.$$

$$\text{Ring Value} := \log(p^e / r(p, e)) = e \log p - \log r(p, e).$$

- These definitions lead to minimizing the number of residues to check modulo N .

- Choosing prime rings to include in N is a variation of the *knapsack problem*, which is NP-complete.

- For a ring with modulus p^e and $r(p, e)$ residues,

$$\text{Ring Size} := \log(p^e) = e \log p.$$

$$\text{Ring Value} := \log(p^e / r(p, e)) = e \log p - \log r(p, e).$$

- These definitions lead to minimizing the number of residues to check modulo N .
- *Prime splitting* is choosing the best e for each p to maximize the Value/Size ratio.

Knapsack

- Choosing prime rings to include in N is a variation of the *knapsack problem*, which is NP-complete.

- For a ring with modulus p^e and $r(p, e)$ residues,

$$\text{Ring Size} := \log(p^e) = e \log p.$$

$$\text{Ring Value} := \log(p^e / r(p, e)) = e \log p - \log r(p, e).$$

- These definitions lead to minimizing the number of residues to check modulo N .
- *Prime splitting* is choosing the best e for each p to maximize the Value/Size ratio.
- Our greedy knapsack algorithm picks the rings of highest value such that the sum of the sizes is roughly $\log N$. For $k = 10$ we'd aim for $\log N$ near $\log 307$.

Knapsack Example with $k = 10$

p	e	$\lfloor \log_p k \rfloor + 1$	$r(p, e)$	<i>filter rate</i>	k in base p
2	4	4	4	0.25	1010 ₂
3	1	3	2	0.666667	101 ₃
7	1	2	4	0.571429	13 ₇
3	3	3	6(12)	0.666667	20 ₅
5	2	2	15	0.6	
7	2	2	6(24)	0.857143	

We ran an algorithm to choose an optimal splitting point (e) for each prime. Both rings are included as options for the knapsack algorithm.

Algorithm Running Time

Theorem.

Under the assumption of the *Uniform Distribution Heuristic* (see the next slide) our new algorithm has a running time of

$$g(k) \exp \left[-\frac{c \cdot k \log \log k}{(\log k)^2} \cdot (1 + o(1)) \right]$$

arithmetic operations, for a constant $c > 0$.

It's possible to prove a sublinear running time with no assumptions.

Approximating $g(k)$

We have $M_k = \prod_{p \leq k} p^{\lceil \log_p k \rceil + 1}$.

R_k counts the acceptable residues, modulo M_k .

$$\hat{g}(k) := M_k / R_k.$$

Approximating $g(k)$

We have $M_k = \prod_{p \leq k} p^{\lceil \log_p k \rceil + 1}$.

R_k counts the acceptable residues, modulo M_k .

$$\hat{g}(k) := M_k / R_k.$$

Uniform Distribution Heuristic (UDH)

The R_k acceptable residues are uniformly distributed modulo M_k .

Approximating $g(k)$

We have $M_k = \prod_{p \leq k} p^{\lceil \log_p k \rceil + 1}$.

R_k counts the acceptable residues, modulo M_k .

$$\hat{g}(k) := M_k / R_k.$$

Uniform Distribution Heuristic (UDH)

The R_k acceptable residues are uniformly distributed modulo M_k .

Theorem.

The UDH implies that, with high "probability",

$$\hat{g}(k)/k < g(k) < \hat{g}(k) \cdot k,$$

or

$$\log g(k) = \log \hat{g}(k) + O(\log k).$$

$g(k)$ versus $\hat{g}(k)$ (logscale)

Zooming in: for(k=200; k<250; k++)

Statistical Tests for Uniformity

Thanks to Dr. Rasitha Jayasekare for her help with this.

Approximating $g(k)$

Define $G(x, k)$ to be the number of $n \leq x$ such that $\binom{n}{k}$ has no prime divisors $\leq k$.

Approximating $g(k)$

Define $G(x, k)$ to be the number of $n \leq x$ such that $\binom{n}{k}$ has no prime divisors $\leq k$.

Theorem.

$$G(x, k) = \frac{x}{\hat{g}(k)}(1 + o(1)).$$

This also suggests that $g(k)$ is near $\hat{g}(k)$.

The Five Conjectures

Ecklund, Erdős, and Selfridge (1974) conjectured the following:

Conjecture	$g(k)$	$\hat{g}(k)$
(1) $\limsup_{k \rightarrow \infty} g(k+1)/g(k) = \infty$	?	TRUE
(2) $\liminf_{k \rightarrow \infty} g(k+1)/g(k) = 0$	?	?
(3) $g(k)$ is super-polynomial in k	TRUE	TRUE
(4) $\lim_{k \rightarrow \infty} g(k)^{1/k} = 1$	?	TRUE
(5) $g(k) < \exp[ck/\log k]$ for a constant $c > 0$	?	TRUE

- Granville and Ramaré (1996) proved (3) by showing $g(k) \gg k^{c\sqrt{\log k / \log \log k}}$.
- Konyagin (1998) has the best lower bound, $g(k) \gg k^{c \log k}$.

New Results for $\hat{g}(k)$

Theorem 1.

$$\limsup_{k \rightarrow \infty} \frac{\hat{g}(k+1)}{\hat{g}(k)} = \infty.$$

We prove the ratio $\hat{g}(k+1)/\hat{g}(k) \gg \log k$ when $k+1$ is prime.

New Results for $\hat{g}(k)$

Theorem 1.

$$\limsup_{k \rightarrow \infty} \frac{\hat{g}(k+1)}{\hat{g}(k)} = \infty.$$

We prove the ratio $\hat{g}(k+1)/\hat{g}(k) \gg \log k$ when $k+1$ is prime.

Theorem 2.

$$0.525 \dots + o(1) \leq \frac{\log \hat{g}(k)}{k/\log k} \leq 1 + o(1).$$

$$\exp(0.525k/\log k) \leq \hat{g}(k)^{1+o(1)} \leq \exp(k/\log k).$$

Upper and lower bounds

Main Theorem Proof: Three Amigos

For prime p , write k in base p :

$$k = \sum_{i=0}^{\lfloor \log_p k \rfloor} a_{ip} p^i.$$

Main Theorem Proof: Three Amigos

For prime p , write k in base p :

$$k = \sum_{i=0}^{\lfloor \log_p k \rfloor} a_{ip} p^i.$$

$$\hat{g}(k) = \frac{M_k}{R_k} = \frac{\prod_{p \leq k} p^{\lfloor \log_p k \rfloor + 1}}{\prod_{p \leq k} \prod_{i=0}^{\lfloor \log_p k \rfloor} (p - a_{ip})}$$

Main Theorem Proof: Three Amigos

Main Theorem Proof: Blue Part 2

We write the sum as an integral, getting

$$- \int_{k/(a+1)}^{k/a} \frac{\log((a+1)t - k)}{\log t} dt + o(k/\log k)$$

Main Theorem Proof: Blue Part 2

We write the sum as an integral, getting

$$\begin{aligned} & - \int_{k/(a+1)}^{k/a} \frac{\log((a+1)t - k)}{\log t} dt + o(k/\log k) \\ = & - \frac{1}{\log(k/(a+\alpha))} \int_{k/(a+1)}^{k/a} \log((a+1)t - k) dt + o(k/\log k) \end{aligned}$$

Main Theorem Proof: Blue Part 2

We write the sum as an integral, getting

$$\begin{aligned} & - \int_{k/(a+1)}^{k/a} \frac{\log((a+1)t - k)}{\log t} dt + o(k/\log k) \\ = & - \frac{1}{\log(k/(a+1))} \int_{k/(a+1)}^{k/a} \log((a+1)t - k) dt + o(k/\log k) \\ = & - \frac{1}{\log(k/(a+1))} \frac{k(\log(k/a) - 1)}{a(a+1)} + o(k/\log k) \end{aligned}$$

Main Theorem Proof: Blue Part 3

$$\begin{aligned} & \log \left(\prod_{\sqrt{k} < p < k} \frac{p}{p - a_0 p} \right) + o(k / \log k) \\ &= \sum_{a=1}^{\sqrt{k}} \left(\frac{k}{a(a+1)} - \frac{k(\log(k/a) - 1)}{a(a+1) \log(k/(a+\alpha))} \right) \\ &= \frac{k}{\log k} \cdot \sum_{a=1}^{\sqrt{k}} \left(\frac{1 - \log(1 + \frac{\alpha}{a})}{a(a+1)} \right) \cdot \left(1 + O\left(\frac{\log a}{\log k}\right) \right). \end{aligned}$$

Set $\alpha = 0$ to get $c = 1$.

Set $\alpha = 1$ to get $c = 0.525821 \dots$

Summary

- New algorithm with sublinear running time
prime splitting, knapsack, wheel, parallelized
- Computed $g(k)$ for $200 < k \leq 357$
- Defined $\hat{g}(k)$, UDH implies $g(k) \approx \hat{g}(k)$
- Proved Conjectures 1, 3-5 for $\hat{g}(k)$

Future/Continuing Work

- Compute more $g(k)$ values
- CUDA code adaptation and new GPU hardware
- Conjecture (2) for $\hat{g}(k)$
- Better Knapsack algorithms (Brianna's Honor's thesis?)
- Algorithm tweaking
- Narrow the constant range in the exponent for $\hat{g}(k)$

Thank you!

"Ha! Webster's blown his cerebral cortex."
